

# Nuclear magnetic resonance spectroscopy

## I. $^1\text{H}$ NMR

Reading:

Pavia

Chapter 5.8-5.19

Chapter 7.1-7.3, 7.5, 7.6, 7.7 A-C and F, 7.8-7.10

Chapter 8.1, 8.2 A and C

# 1. Chemical equivalence

- protons in chemically identical environments - are chemically equivalent
  - exhibit the same  $\delta$
- equivalence through symmetry considerations

1 signal for 12  $^1\text{H}$

1 signal for 6  $^1\text{H}$

- obvious non-equivalence

2 sets:

1 signal for 6  $^1\text{H}$  in  $\text{CH}_3$

1 signal for 4  $^1\text{H}$  in  $\text{CH}$

2 sets:

1 signal for 6  $^1\text{H}$  in  $\text{OCH}_3$

1 signal for 4  $^1\text{H}$  in  $\text{CH}_2$

2 sets:

1 signal for 3  $^1\text{H}$  in  $\text{CH}_3$

1 signal for 3  $^1\text{H}$  in  $\text{OCH}_3$

## Example

Chemical and magnetic equivalence: Proton signal is a singlet

*plane of symmetry*

*plane of symmetry*

*axis of symmetry*

*axis of symmetry*

*plane of symmetry*

magnetic inequivalence:

complicated spectrum:  
will not discuss!

# 1. Chemical equivalence continued

- spectral regions

- chemical environment of the  $^1\text{H}$  is important:
  - electronegativity effects
  - hybridization effects
  - H-bonding effects
  - magnetic anisotropy effects

see p. A-8 ff

## 2. Integration

- determines the number of equivalent  $^1\text{H}$  for a signal
- determined through the area under the signal
  - given through a step trace (need a ruler!)
- provides first important label

55.5 : 22 : 32.5  
2.5 : 1 : 1.5  
5 : 2 : 3

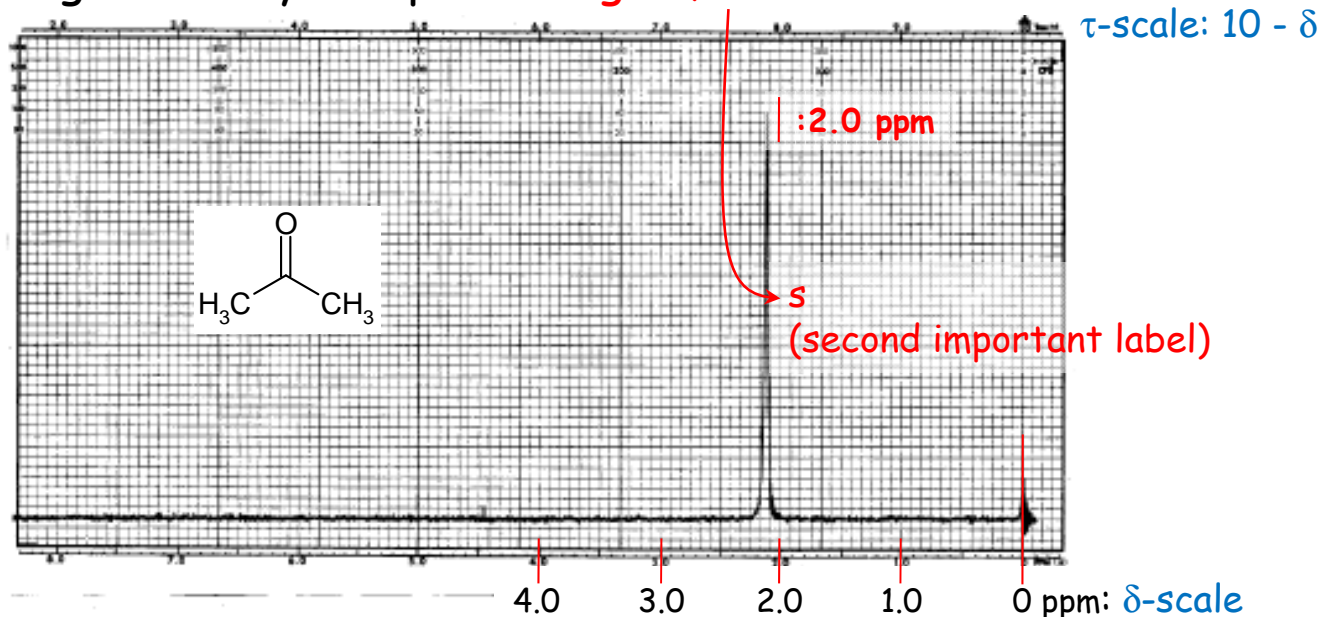

⇒ proton count:  
total of 10  $^1\text{H}$  (at least)!

digital information:

### 3. Simple (singlet) spectra

- signal is only one peak: **singlet, s**

reported:  
2.1 s (6H)

reported:  
2.0 s (3H)  
3.65 s (3H)

### 3. Simple spectra continued

integration:  
1.5 : 1 or  
3 : 2 or revised (!)  
6 : 4

reported:  
2.55 s 4H  
3.65 s 6H  
⇒ for a total  
of 10 <sup>1</sup>H

thoughts:  
- aromatic?  
- U?  
- empirical formula?

reported:  
3.8 s 6H  
6.85 s 2H  
⇒ for a total  
of 8 <sup>1</sup>H

## 4. Estimation of $\delta^1\text{H}$

- from increment systems

- for  $\text{X}-\text{CH}_2-\text{Y}$  (and  $\text{X}-\text{CH}_3$ , where  $\text{Y}=\text{H}$  adds zero)

$$\delta^1\text{H} \text{ (ppm)} = 0.23 + \text{increments for X and Y substituents}$$

see p. A-18

$$\delta^1\text{H}_a = 0.23 + \underset{\text{COOR}}{1.55} + \underset{\text{H}}{0} = 1.78 \text{ ppm (exp. 2.0 ppm) compare: ok}$$

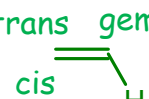

$$\delta^1\text{H}_b = 0.23 + \underset{\text{OCOR}}{3.13} + \underset{\text{H}}{0} = 3.36 \text{ ppm (exp. 3.65 ppm) ok}$$

(appropriate?)

$$\delta^1\text{H}_a = 0.23 + \underset{\text{COOR}}{1.55} + \underset{\text{R}}{0.47^?} = 2.25 \text{ ppm (exp. 2.55 ppm) ok}$$

$$\delta^1\text{H}_b = 0.23 + \underset{\text{OCOR}}{3.13} + \underset{\text{H}}{0} = 3.36 \text{ ppm (exp. 3.65 ppm) ok}$$

- for 

$$\delta^1\text{H} \text{ (ppm)} = 5.25 + \text{increments for gem, trans and cis substituents}$$

see p. A-19

$$\delta^1\text{H}_a = 0.23 + \underset{\text{OCOR}}{3.13^?} + \underset{\text{H}}{0} = 3.36 \text{ ppm (exp. 3.8 ppm) not reliable}$$

$$\delta^1\text{H}_b = 5.25 + \underset{\text{COOR}}{\underset{\text{gem}}{0.84}} + \underset{\text{COOR}}{\underset{\text{cis}}{1.15}} + \underset{\text{H}}{\underset{\text{trans}}{0}} = 7.24 \text{ ppm (exp. 6.85 ppm) ok}$$

## 4. Estimation of $\delta^1\text{H}$ continued

- from an increment system

$$\delta^1\text{H (ppm)} = 7.27 + \text{increments for substituents}$$

see p. A-20

$$\delta^1\text{H}_a = 0.23 + \underset{\text{COOR}}{1.55} + \underset{\text{OC}_6\text{H}_5}{3.23} = 5.01 \text{ ppm (exp. 4.6 ppm) } \text{ok?}$$

$$\delta^1\text{H}_b = 7.27 + 2 \cdot \underset{\text{o-Cl}}{0.03} + \underset{\text{p-Cl}}{(-0.09)} + \underset{\text{m-OR}}{(-0.09)} = 7.15 \text{ ppm (exp. 7.5 ppm) } \text{ok?}$$

$$\delta^1\text{H}_c = 11\text{--}12 \text{ ppm (no increments; from Table 5.4 or p. A-8)}$$

inset;  
problem:  
no scale given!

Not overly important  
for us

## 5. Magnetic anisotropy

- phenomenon observed for protons on or near  $\pi$ -systems
- mobile  $\pi$ -electrons create local magnetic fields
- shielding (+) and deshielding (-) regions
- unusual chemical shifts

reasoning:

general shielding observations:

Fig. 5.21

## 6. Spin-spin coupling

- between sets of chemically equivalent protons: signals are no longer singlets
- signal can be split into (use the **red** labels):

- 2 lines: doublet, **d**
- 3 lines: triplet, **t**
- 4 lines, quartet, **q**
- 5 lines, quintet, **quint**
- 6 lines, sextet, **sext**
- 7 lines, septet, **sept**

# of lines depends on the number of neighbouring  $^1\text{H}$ :  
n+1 rule:

n+1 lines in the signal for n equivalent neighbouring  $^1\text{H}$

- protons can couple over

- 2 bonds:  $^2\text{J}$  coupling

Will get back to this in detail later

- 3 bonds:  $^3\text{J}$  coupling

- 4 bonds or more:  $^4\text{J}$ ,  $^5\text{J}$  coupling or "long-range" coupling (mostly not observed)

but observed across multiple bonds:

## 6. Spin-spin coupling continued

- signal multiplicity (number of lines) explained:

$\uparrow$   $\uparrow$   $^1\text{H}$  sees *one*  $^1\text{H}$  on the next carbon atom:

$\downarrow\downarrow$   $\uparrow\uparrow$  - total of 2 different spin situations:  $\uparrow\uparrow$  and  $\downarrow\downarrow$

- signal for  $^1\text{H}$  splits into 2 lines: doublet

equal probability

⇒ same area/height

⇒ intensity ratio in signal 1:1

total spin observed by  $^1\text{H}$ :  $+\frac{1}{2} \quad -\frac{1}{2}$

↑↑ ↑  $^1\text{H}$  sees **two**  $^1\text{H}$  on the next carbon atom:

$\uparrow\uparrow\downarrow$   $\uparrow\uparrow$  - total of 3 different spin situations

$\downarrow\downarrow\uparrow$   $\uparrow\uparrow$  - signal for  $^1\text{H}$  splits into 3 lines: triplet

⇒ intensity ratio in signal 1:2:1

total spin observed by  $^1\text{H}$ : +1 0 -1

## 6. Spin-spin coupling continued

- for  $I = \frac{1}{2}$ , **intensities** of the lines within a signal follow the binomial distribution
- **Pascal's triangle (easily constructed)**

				1						one line only
				1		1				two lines, equal intensities
			1		2		1			three lines, intensity ratio 1:2:1
		1		3		3		1		
	1		4		6		4		1	
1		5		10		10		5		1
1	6		15		20		15		6	1
										septet, outer lines often tough to detect!

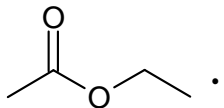

looks like only 5 lines

don't miss the outer lines!

now we can  
predict  $^1\text{H}$  spectra

## Example

Better than  
problem 5.13!

Predict (draw) the  $^1\text{H}$  NMR spectrum for  .  
First list (the calculated)  $\delta$ , multiplicity and integration.

## 7. Spectra with simple multiplets

Do not forget that you need all three labels on a signal!

Table 5.8:  
examples of  
splitting patterns

## 7. Spectra with simple multiplets continued

- multiplet issues

### I. Multiplicity

quint    sext

Fig. 5.41

1.5  
 $\Delta\delta$  0.25 ppm

quint?    sext?

Fig. 5.43

1.5  
 $\Delta\delta$  0.15 ppm

Will discuss later in more detail,  
but for our purposes, these are  
still quint and sext!

## 7. Spectra with simple multiplets continued

- multiplet issues

### II. Skewing in multiplets

- first information on which protons are coupled

## 8. Coupling constant, J

- number assigned to the spread of the lines in a multiplet
- more reliable information on which protons are coupled than skewing
- for two multiplets from coupling protons, J is the same

if this spectrum was taken at 60 MHz:

AX spin system:

- Pople notation for coupling protons
- two chemically different protons,  $\Delta\delta$  is (relatively) large

## 8. Coupling constant, J, continued

Table 5.9:  
generalized J values  
and  
A-13 ff

all  $\leftrightarrow$  spacings are the same,  
 $^3J$  7.5 Hz

$A_2X_3$  spin system:

- Pople notation
- two sets of chemically different protons,  $\Delta\delta$  is (relatively) large

## Example

Assuming that  $^3J$  is greater upon Br-substitution, which structure is correct?

## 8. Coupling constant, J, continued

- origin of the coupling: via the electrons in the bonds  
: interaction between spins of nuclei and electrons

size of J depends on the geometry:

- $^2J$  depends on the HCH **bond angle**: larger J with smaller angle  
(better interaction of  $\sigma$ -orbitals)

$\alpha$  109°  
 $^2J$  12 Hz

$\alpha$  118°  
 $^2J$  5 Hz

Fig. 7.4

- $^3J$  depends on the HCCH **torsion angle**: minimum function at 90°  
(no interaction of  $\sigma$ -orbitals)

Karplus curve

$\phi$  180°  
 $^3J$  12 Hz

$\phi$  60°  
 $^3J$  4 Hz

Fig. 7.7

## 9. First and second order spectra

- Second-order spectra are found for sets of nuclei if  $\Delta\nu/J$  is too small

Fig. 7.44

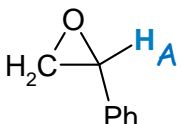

## 10. Non-equivalence within a group

- coupling within a group ( $\text{CH}_2$ , e.g.) when protons are *not* chemically equivalent

all three  $^1\text{H}$  are chemically different

$\Rightarrow$  all will couple amongst each other

$\Rightarrow$  this is *not*  ,  $\text{H}_\text{A}$  does *not* couple into a triplet!

- observed coupling here:  $^3J_{\text{AM}} \neq ^3J_{\text{AX}}, ^2J_{\text{MX}}$

- we expect - three different coupling constants

- signals of different multiplicity than so far

- we can analyse - coupling constants

- appearance of a signal

through tree-diagrams

## 10. Non-equivalence within a group continued

### - analysis with a tree-diagram

simple system:

coupling to one type of  $^1\text{H}$

advanced system:

coupling to two types of  $^1\text{H}$

doublet with  $\text{H}_\text{X} \rightarrow$

doublet with  $\text{H}_\text{M} \rightarrow$

$\Rightarrow 1 \text{ signal, } 4 \text{ lines}$

## 10. Non-equivalence within a group continued

### - two uses of a tree-diagram

towards a spectrum: what does the signal look like?

#### - use larger J first

not like this:

#### - stay symmetrical

: not like this, either!

from a spectrum: what are the coupling constants?

#### - take distance *within* and *between* the "sub-multiplets"

for a dd, measure

"within": distance of lines 1 and 2 or 3 and 4

"between": distance of lines 1 and 3 or 2 and 4

## 10. Non-equivalence within a group continued

- appearance of the spectrum

tree-diagram analysis

example:

$J_{AX}$  appears twice:

- in the signal for  $H_A$
- in the signal for  $H_X$

summarize as:

$^3J_{AX}$  2.6 Hz

$^3J_{AM}$  4.0 Hz

$^2J_{MX}$  5.5 Hz

Fig. 7.31

## 10. Non-equivalence within a group continued

- two practice patterns

spin system:

multiplicities:

tree-diagram (assume  $J_1 > J_2$ ):

spin system:

multiplicities:

tree-diagram:

How do you determine which J is which?

## 10. Non-equivalence within a group continued

- the appearance of a dt as  $J$  changes

# 10. Non-equivalence within a group continued

## - coupling examples in alkenes

$^1\text{H}$  are chemically and magnetically equivalent  
 $\Rightarrow$  s, 2H, no splitting

2 d,  $^3\text{J} \sim 16$  Hz (large)

2 d,  $^3\text{J} \sim 8$  Hz

2 d,  $^2\text{J} \sim 0-5$  Hz

3 dd

Fig. 7.53

Table A6.2

# 11. Protons on oxygen

- 2 issues

I. Lack of coupling

what you might expect to see

- ultrapure sample
- coupling to the OH proton observed

what you usually do see

- ordinary sample
- coupling to the OH proton *not* observed

Fig. 8.3

Fig. 8.2

## 11. Protons on oxygen continued

- Reason that coupling to protons on oxygen is not observed:
  - exchange takes place with other ROH, H<sub>2</sub>O, traces of acid...
  - OH proton is not attached long enough for coupling to be recorded
  - rate of exchange is too great

Examples of fast exchange (high rate):

Example of a slow exchange (low rate):

- for coupling to be observed,  
rate of exchange (1/s)  $\approx$  coupling constant J (Hz)

How would you slow down the rate of exchange?

Cooling?

H-bonding?

## 11. Protons on oxygen continued

- 2 issues

II. Variability in  $\delta$

- ultrapure sample

Fig. 8.3

- ordinary sample

Fig. 8.2

## 11. Protons on oxygen continued

- Reason for the variable  $\delta$ :
  - rapid exchange with  $\text{H}_2\text{O}$ ... (again)
  - OH signal position becomes the weighted average

exact position depends on the amount of water

Fig. 8.4
