

# Multivariate Analysis: Redundancy Analysis (RDA)

BIOL 680 – Alex Engler  
Guest lecture – 11/04/2023

1

---

---

---

---

---

---

---

---

## Outline

Introduction

1. What is a RDA?
2. Constrained and Unconstrained Variances
3. Plotting and interpreting the RDA
4. Variance partitioning
5. Exercise (We will go through a RDA together)
7. Question session

2

---

---

---

---

---

---

---

---

## Introduction

3

---

---

---

---

---

---

---

---

## Multivariate analysis

- The most common multivariate analysis is the Principal Component Analysis (PCA)
- Summarise the colinearity of the variables
- Reduce a n-dimension table to a smaller one

4

---

---

---

---

---

---

---

---

## Multivariate analysis

- Multivariate analysis: when you have a table with many variables:
- Want to understand their potential correlations
- The similarities between individuals
- Summarise complex information into fewer variables

5

---

---

---

---

---

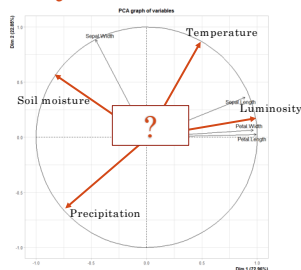

---

---

---

## Multivariate analysis

- What to do when we want to explain a set of variables with another set of variables?  
(example: explaining the plant's morphology by environmental variables)
- We run a Redundancy Analysis (RDA)

6

---

---

---

---

---

---

---

---

# What is an RDA?

How do we build an RDA

7

---

---

---

---

---

---

---

---

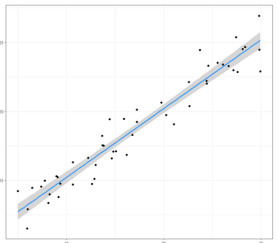

## Multiple regressions

- Multiple linear regression

$$Y \sim a + b_1X_1 + b_2X_2 + \dots + b_nX_n + e$$

In this case:

- Y : response variable
- $X_n$  : explanatory variables
- a: the intercept
- $b_n$ : the slope related to  $Y_n$
- e: the residuals

8

---

---

---

---

---

---

---

---

## Multiple regressions

- An RDA: a direct extension of the multiple linear regression with multivariate data

Y

Set of response variables

~

X

Set of explanatory variables

BE CAREFUL YOU SHOULD HAVE THE SAME NUMBER OF OBSERVATIONS (ROWS) IN BOTH TABLES

9

---

---

---

---

---

---

---

---

### Multiple regressions

- An RDA: a direct extension of the multiple linear regression with multivariate data

Row = observation

Y

N response variables

X

M explanatory variables

Row = observation

BE CAREFUL YOU SHOULD HAVE THE SAME NUMBER OF OBSERVATIONS (ROWS) IN BOTH TABLES

10

---

---

---

---

---

---

---

---

### Multiple regressions

- FIRST STEP : regress each response variable by the explanatory variables

$$Y_1 \sim X_1 + X_2 + \dots + X_m + \epsilon_1$$

$$Y_2 \sim X_1 + X_2 + \dots + X_m + \epsilon_2$$

$$Y_3 \sim X_1 + X_2 + \dots + X_m + \epsilon_3$$

⋮

$$Y_n \sim X_1 + X_2 + \dots + X_m + \epsilon_n$$

11

---

---

---

---

---

---

---

---

### Multiple regressions

- STEP 2: extract the fitted values and the residuals for each linear model

$$Y_1 \sim X_1 + X_2 + \dots + X_m + \epsilon_1$$

$$Y_2 \sim X_1 + X_2 + \dots + X_m + \epsilon_2$$

$$Y_3 \sim X_1 + X_2 + \dots + X_m + \epsilon_3$$

⋮

$$Y_n \sim X_1 + X_2 + \dots + X_m + \epsilon_n$$

Matrix of fitted values

Matrix of residuals

12

---

---

---

---

---

---

---

---

### Multiple regressions

- STEP 3: pca on the fitted values

$\hat{Y}$   $\xrightarrow{\text{PCA}}$   $U$

Matrix of eigen-values  
(creation of the new multivariate space)

13

---

---

---

---

---

---

---

---

### Multiple regressions

- STEP 4: projection of the raw data and fitted values in the new space

$X$   $\xrightarrow{\text{Projection}}$   $Z$

$Y$   $\xrightarrow{\text{Projection}}$   $F$

$U$

New coordinates for the explanatory variables in the new space

New coordinates for the response variables in the new space

14

---

---

---

---

---

---

---

---

### Multiple regressions

- STEP 4: projection of the raw data and fitted values in the new space

Rows: sites

$F$   $Z$

New coordinates for the response variables in the new space

New coordinates for the explanatory variables in the new space

15

---

---

---

---

---

---

---

---

### Multiple regressions

• STEP 5: pca on the residuals

Matrix of eigen-values  
(creation of the new space  
for residuals)

Projection of the  
residuals in the new  
space

16

---

---

---

---

---

---

---

---

### How do we build an RDA

An RDA is two PCAs in a trenchcoat:

- One on the fitted values (summarising the results of multiple linear régressions)
- One on the residuals (summarising the variability that was not catch by the linear régressions)

© 2010/2011

17

---

---

---

---

---

---

---

---

## The results of the RDA

18

---

---

---

---

---

---

---

---

## Constrained and unconstrained parts of the RDAs

An RDA is two PCAs in a trenchcoat:

- The fitted model (constrained)
- The residuals (unconstrained)

19

---

---

---

---

---

---

---

---

## Constrained and unconstrained variance

When you run a RDA, you will have this table :

	Inertia	Proportion	Rank
Total	4.57296	1.00000	
Constrained	4.25228	0.92987	4
Unconstrained	0.32068	0.07013	4

Inertia is variance

Inertia is synonym to variance

**Total** is the total variance of your response variables  
**Constrained** is the variance explained by your linear model  
**Unconstrained** is the remaining variance that is not explained by the model

20

---

---

---

---

---

---

---

---

## Constrained and unconstrained axis

Eigenvalues for constrained axes:			
RDA1	RDA2	RDA3	RDA4
4.090	0.159	0.002	0.001

Eigenvalues for unconstrained axes:			
PC1	PC2	PC3	PC4
0.21289	0.08174	0.02178	0.00428

Similarly to the PCA, you can look at the variance explained by each axis:

The constrained axis are the variance for the fitted model; the sum of the « eigenvalues » should equal to the inertia of the constrained model

The unconstrained axis is variance of the residuals. We don't usually interpret them.

21

---

---

---

---

---

---

---

---

## The performance of the RDA

- Similarly to a regular linear regression, you have a  $R^2$ , that represents the overall fit of the models (the adjusted  $R^2$  take in account the number of explanatory variables)
- There is F-statistics that compare the model with a null model
- $H_0$  : the strength of the linear relationship, measured by the canonical  $R^2$ , is not larger than the value that would be obtained for unrelated Y and X matrices of the same sizes
- We can test for the whole model or for each axis of the model or for each explanatory variables !

---

---

---

---

---

---

---

---

22

## Plotting an RDA

---

---

---

---

---

---

---

---

23

### 2 types of plot in RDA

- Scaling 1 or distance triplot
- The distance between sites (points) is an approximation of the euclidean distance
- The relationship between explanatory variables is preserved
- The angles between explanatory variables (red arrows) are meaningless

---

---

---

---

---

---

---

---

24

### 2 types of plot in RDA

- Scaling 2 or correlation triplot
- The angle of two variables is an approximation of the correlations between the two variables
- The distance between two objects does not reflect their Euclidean distance

25

---

---

---

---

---

---

---

---

### Summary

- An RDA is just a linear regression with multiple response variables and multiple explanatory variables

$$Y \sim X + RES$$

- An RDA is two PCA: one that will capture the variance of the linear models and the other the residuals
- You can either plot accurately the distance between observations or the relationships between the response variables. In both case, the correlations between response and explanatory variables is conserved

26

---

---

---

---

---

---

---

---

## Variance partitioning in RDAs

27

---

---

---

---

---

---

---

---

### Variance partition

- Type of analysis for RDAs when we separate the explanatory variables in several sets of explanatory variables
- Goal: Understand what is the variance explained by a specific set of variables
- Very useful to distinguish the effects of variables when there are confounding variables

The diagram shows three colored boxes: a dark brown box labeled 'Y', a light brown box labeled 'X<sub>1</sub>', and a red box labeled 'X<sub>2</sub>'. They are arranged horizontally with a tilde symbol (~) between 'Y' and 'X<sub>1</sub>', and a plus sign (+) between 'X<sub>1</sub>' and 'X<sub>2</sub>'.

28

---

---

---

---

---

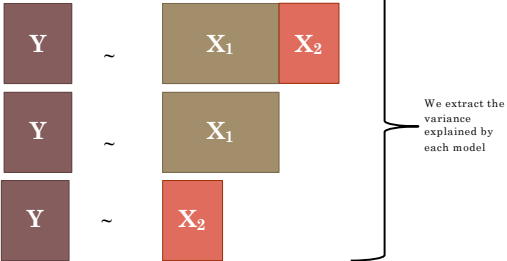

---

---

---

### Variance partition

- It consists in three consecutive RDAs

The diagram shows three rows of boxes. The first row has a dark brown box 'Y' followed by a tilde '~', then a light brown box 'X<sub>1</sub>' and a red box 'X<sub>2</sub>'. The second row has a dark brown box 'Y' followed by a tilde '~', then a light brown box 'X<sub>1</sub>'. The third row has a dark brown box 'Y' followed by a tilde '~', then a red box 'X<sub>2</sub>'. A large right-facing curly bracket groups these three rows, with the text 'We extract the variance explained by each model' to its right.

29

---

---

---

---

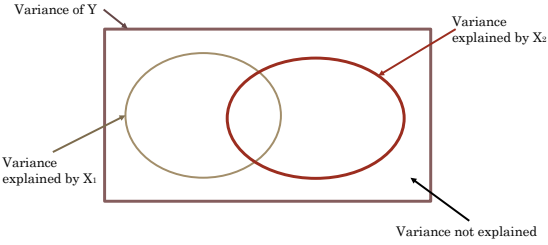

---

---

---

---

### Variance partition

The diagram is a Venn diagram within a rectangular frame. It features two overlapping circles: a light brown circle on the left and a red circle on the right. Labels with arrows point to different parts of the diagram: 'Variance of Y' points to the top of the frame; 'Variance explained by X<sub>1</sub>' points to the left circle; 'Variance explained by X<sub>2</sub>' points to the right circle; and 'Variance not explained' points to the bottom of the frame.

30

---

---

---

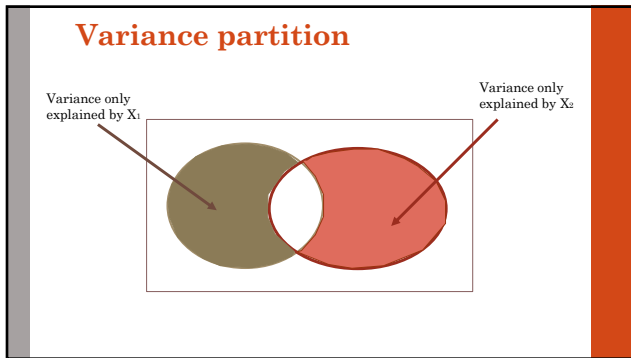

---

---

---

---

---

31

---

---

---

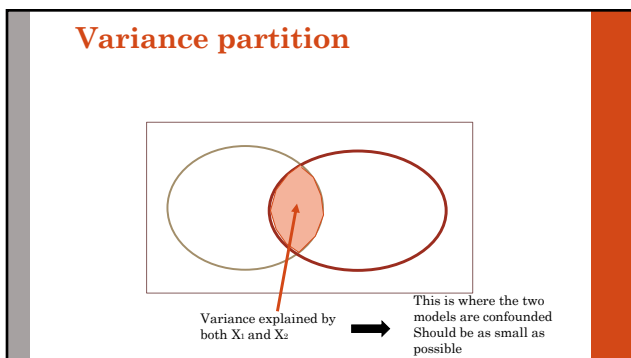

---

---

---

---

---

32

---

---

---

---

---

---

---

---

### Summary of the variance partitioning

- It is a method to understand where confounding effects are in our models : How much of the variance could have been explained by different variables ?
- Can be very useful when you have geographically structured data
  
- What to do when you have a lot of shared variance between two variables:
- You can not separate the effect of one or the other
- You have to redesign your experiment/data collection to be able to separate the effects of the two variables

33

---

---

---

---

---

---

---

---

---

---

---

---

---

---

**Exercice : How the environmental variables impact the communities composition ?**

In 1989: Daniel Brocard sampled 75 sites and described the mites communities on those sites

There were 35 species recorded in total.

He measured 5 environmental variables

Goal: Which environmental variables drive the species composition of the mites communities

36

---

---

---

---

---

---

---

---

What can you tell me about the correlations between the response and explanatory variables?

---

---

---

---

---

---

---

37

What can you tell me about the correlations between the response and explanatory variables?

We are in Scaling 1 :

- The distances between sites are preserved
- One site is very different from the others and it probably due to the presence of one species

---

---

---

---

---

---

---

38

What can you tell me about the correlations between the response and explanatory variables?

---

---

---

---

---

---

---

39

### What can you tell me about the correlations between the response and explanatory variables?

We are in scaling 2:  
 We can only interpret the angles between variables  
 → Water Content drive the first axis  
 → Topology, and different substrate driving the second axis.

40

---

---

---

---

---

---

---

---

### Are there significant environmental variables that drive the mite communities?

```
Model: rda(formula = mite ~ SubstDens + MatrCont + Substrate + Shrub + Topo, data = mite.env)
Df Variance F Pr(>F)
SubstDens 1 349.5 1.2804 0.009
MatrCont 1 1628.1 58.2824 0.000 **
Substrate 6 801.7 1.2540 0.112
Shrub 2 57.7 0.2207 0.953
Topo 1 81.6 0.7660 0.425
Residual 38 6179.8
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

41

---

---

---

---

---

---

---

---

### What are the performance of the RDA

How much variance is explained by our model? How much is left unexplained?

	Inertia	Proportion	Rank
Total	9098.5913	1.0000	
Constrained	2918.8096	0.3208	11
Unconstrained	6179.7817	0.6792	35

Inertia is variance

Are the results of our model significant?

Test for the model significance

```
Model: rda(formula = mite ~ SubstDens + MatrCont + Substrate + Shrub + Topo, data = mite.env)
Df Variance F Pr(>F)
Model 11 2918.8 2.4904 0.098 .
Residual 38 6179.8
---
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

42

---

---

---

---

---

---

---

---

### What are the performance of the RDA

How much variance is explained by our model? How much is left unexplained ?

	Inertia	Proportion	Rank
Total	5096.3913	1.0000	
Constrained	2918.8096	0.5728	14
Unconstrained	2177.5817	0.4272	35
Inertia is variance			

The model explains 32% of the variance

Are the results of our model significant?  
Test for the model significance

```
Model: rda(formula = mite ~ SubsDens + MatrCont + Substrate + Shrub + Topo, data = mite.env)
Df Variance F Pr(>F)
Model 11 2918.8 2.4904 0.098 .
Residual 38 6179.8
```

Not significant

---

---

---

---

---

---

---

---

---

---

43

### TIPS TO RUN A RDA

- SCALE YOUR EXPLANATORY AND RESPONSE VARIABLES (avoid to detect effect solely due to difference of units)
- Try to reduce as possible collinearity between explanatory variables as much as possible before running the rda (with a PCA, for instance)
- Make sure you have the good number of observations in both set of variables
- Don't forget to check the percentage of explained variance
- You can do a variance partition to disentangle the specific effect of one set of variables

---

---

---

---

---

---

---

---

---

---

44

### Bibliography
