

LECTURE TOPICS:

TODAY'S CLASS: continue Ch.7

NEXT CLASS: finish Ch.7

(1)

7.3 Atomic line spectra & Niels Bohr...

**WHITE LIGHT:** combination of ALL visible wavelengths  
if separate wavelengths using a prism: "CONTINUOUS SPECTRUM"

**WHY?** Light enters different medium  $\Rightarrow$  rays are refracted  
 $\rightarrow$  shorter  $\lambda$  light bends more (for more detail, take physics)

Zumdahl's Figure 7.4  
See K&T Figure 7.7 & so on...

(2)

## Atomic spectrum of PURE H<sub>2</sub>: a LINE spectrum...

Expose hydrogen (H<sub>2</sub>) to high-energy spark

H<sub>2</sub> molecules absorb energy ⇒ breaks H-H bonds

Resulting H atoms are "excited"

release extra energy as PHOTONS

+ other, non-visible lines: some in UV region, some in IR region...

"atomic emission spectrum" = light of specific energies ( $\lambda$ 's)

Application = glowing electric "neon" signs

- for a molecular substance like elemental hydrogen, relaxed atoms at end reform H<sub>2</sub> or react with other stuff (= loss)
- for noble gases: unreactive free atoms ⇒ no losses ⇒ useful...

## Why are atomic spectra LINE SPECTRA ?

E.g., ATOMIC SPECTRUM OF NEON: looks red-orange to the eye

When an atom decreases its energy level by a discrete increment  $\Delta E$  ⇒ a PHOTON is emitted with  $E = h\nu = \Delta E$

Hydrogen's emission spectrum in detail Figure 7.12

**The Bohr Model of the H atom (incorrect)**  
 ...1<sup>st</sup> recognition that quantization applies to atomic structure!!

**Niels Bohr**  
 (1885- 1962)  
 Danish physicist

**BOHR'S MODEL:** The  $e^-$  in an H atom can move around the nucleus in *circular orbits* of **ALLOWED** energies

"n" is now known as the **principal quantum number** for the  $e^-$   $\Rightarrow$  describes  $e^-$ 's energy

$$E = - \left( \frac{Rhc}{n^2} \right)$$

- $E$  = energy of specific energy level,  $n$
- $n$  = an integer (*name of energy level...*)
- $R$  = Rydberg constant =  $1.0974 \times 10^7 \text{ m}^{-1}$
- $h$  = Planck's constant
- $c$  = speed of light in vacuum

(6) Energy must be **ABSORBED** (to move  $e^-$  to higher  $E$  state) or **EMITTED** (to move  $e^-$  to lower  $E$  state)

## Hydrogen's $e^-$ transition energies can be calculated

$$\Delta E = -Rhc \left( \frac{1}{n_{\text{final}}^2} - \frac{1}{n_{\text{initial}}^2} \right)$$

$Rhc$ : per mole: 1312 kJ/mol  
per electron:  $2.181 \times 10^{-18}$  J

*E.g., Exciting an electron:* in one H atom from the  $n=2$  to  $n=4$  state:

$$\Delta E = - (2.181 \times 10^{-18} \text{ J}) \times \left[ \left( \frac{1}{4^2} \right) - \left( \frac{1}{2^2} \right) \right]$$

$$= + 4.089 \times 10^{-19} \text{ J} \Rightarrow \text{absorb a 486nm photon (bluish-green...)}$$

*c.f., Ionizing an atom:* eject  $e^-$  from atom (from  $n=1$  to " $n=\infty$ " state):

$$\Delta E = - (2.181 \times 10^{-18} \text{ J}) \times \left[ \left( \frac{1}{\infty^2} \right) - \left( \frac{1}{1^2} \right) \right]$$

$$= + 2.181 \times 10^{-18} \text{ J} = \text{ionization energy (91nm photon, deep UV)}$$

## Bohr's model: good and bad...

- Could explain experimental observations for H & He<sup>+</sup>:
  - Line spectrum
  - Ionization energy
- & predict wavelengths of unseen lines in spectra (correctly)
- INTRODUCED CONCEPT OF ENERGY QUANTIZATION IN DESCRIBING ATOMIC STRUCTURE !

### DOWNFALL:

- Model does not work for species with >1 electron
- ⇒ **Idea of planet-like orbits is incorrect...**

## ASSIGNED READINGS

- **BEFORE NEXT CLASS:**

Read Ch.7 up to section 7.3
