

**NOTE: the answers from Ch.18 have not been verified. Please report any errors.**

Ch.	Q#	Answer/Comments
18	2a	pH increases ( $\text{C}_2\text{O}_4^{2-}$ is a weak base; what you get when lose 2 H+ from oxalic acid)
	2b	pH decreases ( $\text{NH}_4^+$ , a weak acid, is being added to a solution containing strong acid)
	2c	no change ( $\text{Na}^+$ is not acid or base; $\text{Cl}^-$ is essentially not basic since is conjugate base of strong acid)
18	4	$[\text{CH}_3\text{CO}_2^-] = 0.190 \text{ M}$ ; use ICE table and $K_a$ expression; solve for $x = [\text{H}_3\text{O}^+] = 1.4 \times 10^{-5} \text{ M} \Rightarrow \text{pH} = 4.85$
18	8a	$[\text{CH}_3\text{CHOHCO}_2\text{H}] = 0.0491 \text{ M}$ ; use ICE table & $K_a$ expression; solve $x = [\text{H}_3\text{O}^+] = 2.9 \times 10^{-4} \text{ M} \Rightarrow \text{pH} = 3.54$
	8b	The buffer solution has a higher pH than the original lactic acid solution ( $\text{pH} = 2.43$ ) because a weak base ( $\text{CH}_3\text{CHOHCO}_2^-$ ) was added to the lactic acid solution.
18	10	$[\text{H}_3\text{O}^+] = 10^{-\text{pH}} = 1.0 \times 10^{-9} \text{ M} = \text{eqm value}$ ; use $K_a$ expression, solve for $[\text{NH}_4^+] = 0.18 \text{ M} \Rightarrow 4.8 \text{ g NH}_4\text{Cl total}$
18	14a	$\text{p}K_a = 7.21$ ; calculate moles of $\text{Na}_2\text{PO}_4$ (=0.03999mol; conj.base) and $\text{KH}_2\text{PO}_4$ (=0.009994mol; conj.acid) use Henderson-Hasselbalch equation ("H.-H. eqn"): solve for pH of buffer = 7.81
	14b	Given pH, use H.-H. eqn solve for ratio of conj.base to conj.acid = 1.3 / 1 Given # moles of $\text{H}_2\text{PO}_4^- = 0.03999\text{mol}$ , calculate 0.032 mol $\text{H}_2\text{PO}_4^-$ To prepare: need 4.3g total of $\text{KH}_2\text{PO}_4$ ...but already have 1.360g in buffer $\Rightarrow$ need to add 2.9g more.
18	16a	$\text{H}_3\text{PO}_4 / \text{NaH}_2\text{PO}_4$ $\text{p}K_a$ of $\text{H}_3\text{PO}_4 = 2.12$
	16b	$\text{NaH}_2\text{PO}_4 / \text{Na}_2\text{HPO}_4$ $\text{p}K_a$ of $\text{H}_2\text{PO}_4^- = 7.21$
	16c	$\text{Na}_2\text{HPO}_4 / \text{Na}_3\text{PO}_4$ $\text{p}K_a$ of $\text{HPO}_4^{2-} = 12.44$ The best choice here is (b), sodium dihydrogen phosphate-sodium hydrogen phosphate buffer.
18	22	using H.-H. eqn: buffer's initial pH = 9.22 Calculate moles of $\text{NH}_3$ (0.0135mol) and $\text{NH}_4^+$ (0.0146mol) in buffer and NaOH added (0.00200mol) Note total volume after adding base = 0.100L Reaction: $\text{OH}^-$ will consume $\text{NH}_4^+$ to yield water and $\text{NH}_3$ ; now have 0.0126mol $\text{NH}_4^+$ , 0.0155mol $\text{NH}_3$ New pH = 9.34; change in pH was 0.12 pH units, increased because added base...
18	24a	$[\text{C}_6\text{H}_5\text{CO}_2\text{H}] = 0.0192 \text{ M}$ initially; use ICE table & $K_a$ to solve for $x = [\text{H}_3\text{O}^+] = 0.0011 \text{ M} \Rightarrow \text{pH} = 2.96$
	24b	Reaction: add known #moles base: calculate how much $\text{C}_6\text{H}_5\text{CO}_2\text{H}$ is consumed & $\text{C}_6\text{H}_5\text{CO}_2^-$ formed New initial $[\text{C}_6\text{H}_5\text{CO}_2^-] = 0.0163\text{M}$ ; and realize system will reequilibrate. Calculate $K_b = K_w/K_a = 1.6 \times 10^{-10}$ ; use ICE table & $K_b$ to solve for $x = [\text{OH}^-] = 1.6 \times 10^{-6} \text{ M}$ Then, $[\text{H}_3\text{O}^+] = K_w/[\text{OH}^-] = 6.2 \times 10^{-9} \text{ M}$ ; note $[\text{Na}^+] = [\text{C}_6\text{H}_5\text{CO}_2^-] = 0.0163 \text{ M}$
	24c	pH = 8.21
18	26a	$[\text{C}_6\text{H}_5\text{NH}_2] = 0.180 \text{ M}$ based on stoichiometry with HCl...
	26b	total volume = 0.0507 L; so new $[\text{C}_6\text{H}_5\text{NH}_2] = 0.0887 \text{ M}$ find $K_a = K_w/K_b = 2.5 \times 10^{-5}$ ; use ICE table & $K_a$ to solve for $x = [\text{H}_3\text{O}^+] = 0.0015 \text{ M}$
	26c	pH = 2.83

Ch.	Q#	Answer/Comments												
18	30a	initial pH: use $K_a$ and ICE table to solve for $x = [H_3O^+] = 4.5 \times 10^{-6} \text{ M} \Rightarrow \text{pH} = 5.35$												
	30b	Half-way to the equivalence point: have added $\frac{1}{2}$ the stoichiometric quantity, so $[HCN] = [CN^-]$ thus, the pH we would observe would be equal to the $\text{p}K_a$ of the weak acid, = 9.40 → this is the inflection point in the buffer region of the titration curve												
	30c	When 95% of the NaOH has been added: have converted 95% of HCN to $CN^-$ - thus: have 0.0012 mol $CN^-$ and $6 \times 10^{-5}$ mol HCN present in the same volume of solution so: $\text{pH} = \text{p}K_a + \log(CN^-/HCN) = 10.7$ by using moles instead of [ ]'s because V's would cancel out												
	30d	volume NaOH added to reach equivalence point = 17 mL												
	30e	At equivalence point: $CN^-$ equilibrates with water... $[CN^-]$ starts at 0.030 M (remember new total V) Find $K_b = K_w/K_a = 2.5 \times 10^{-5}$ ; use ICE table & $K_b$ to solve for $x = [OH^-] = 8.7 \times 10^{-4} \text{ M}$ $\text{pH} = 14 - \text{pOH} = 10.94$												
	30f	alizarin yellow R (from Zumdahl's table 15.8) would be suitable since starts turning orange at pH 11												
	30g	when have added 105% required NaOH: pH depends primarily on the excess $OH^-$ added. Excess = 5% molar excess of $OH^-$ ...ie calculate 5% of (#moles of HCN) to find extra moles of $OH^- = 6 \times 10^{-5}$ mol $OH^-$ excess. Note we also need to figure out what total volume of NaOH solution added to get to this point. Then, calculate pH of solution with $6 \times 10^{-5}$ mol/0.042 L $OH^- \Rightarrow \text{pH} = 14 - \text{pOH} = 11.17$												
18	32	<table border="0"> <tr> <td>titration</td> <td>pH at equivalence point</td> <td>possible indicator</td> </tr> <tr> <td><math>HCO_3^-</math> titrated with HCl</td> <td>pH &lt; 7 (about 3-4)</td> <td>bromocresol green</td> </tr> <tr> <td>HClO with NaOH</td> <td>pH &gt; 7 (about 10-11)</td> <td>thymolphthalein</td> </tr> <tr> <td><math>(CH_3)_3N</math> with HCl</td> <td>pH &lt; 7 (about 5-6)</td> <td>methyl red</td> </tr> </table>	titration	pH at equivalence point	possible indicator	$HCO_3^-$ titrated with HCl	pH < 7 (about 3-4)	bromocresol green	HClO with NaOH	pH > 7 (about 10-11)	thymolphthalein	$(CH_3)_3N$ with HCl	pH < 7 (about 5-6)	methyl red
titration	pH at equivalence point	possible indicator												
$HCO_3^-$ titrated with HCl	pH < 7 (about 3-4)	bromocresol green												
HClO with NaOH	pH > 7 (about 10-11)	thymolphthalein												
$(CH_3)_3N$ with HCl	pH < 7 (about 5-6)	methyl red												
18	36a	soluble (most nitrate salts are soluble)												
	36b	insoluble (most hydroxide salts are insoluble)												
	36c	soluble (most chloride salts are soluble)												
	36d	insoluble (most sulfide salts are insoluble)												
18	38a	$PbSO_4(s) \rightleftharpoons Pb^{2+}(aq) + SO_4^{2-}(aq) \quad K_{sp} = [Pb^{2+}][SO_4^{2-}]$												
	38b	$BaF_2(s) \rightleftharpoons Ba^{2+}(aq) + 2F^-(aq) \quad K_{sp} = [Ba^{2+}][F^-]^2$												
	38c	$Ag_3PO_4(s) \rightleftharpoons 3Ag^+(aq) + PO_4^{3-}(aq) \quad K_{sp} = [Ag^+]^3[PO_4^{3-}]$												
18	42	$[Ca^{2+}] = 0.0140 \text{ M} \Rightarrow K_{sp} = [Ca^{2+}][OH^-]^2 = 5.5 \times 10^{-5}$												
18	44	$\text{pOH} = 1.32$ ; $[OH^-] = 0.048 \text{ M}$ ; $[Ca^{2+}] = \frac{1}{2} [OH^-] = 0.024 \text{ M}$ ; $\Rightarrow K_{sp} = 5.5 \times 10^{-5}$												
18	46	$K_{sp} = [Au^+][Cl^-] = x^2 \Rightarrow x = 4.5 \times 10^{-7} \text{ M} = [Au^+]$												
18	50	$K_{sp} = [Pb^{2+}][SO_4^{2-}] = x^2 \Rightarrow x = 1.6 \times 10^{-4} \text{ M} = [Pb^{2+}] = \text{concentration of dissolved } PbSO_4 \text{ since } 1:1$ thus: use that conc. to find mass of lead sulfate dissolved = 12 mg in 1 L												
18	52a	AgSCN -- note: can directly compare $K_{sp}$ s when compounds have same ratios of cations to anions												
	52b	$SrSO_4$												
	52c	$PbI_2$ (caution: solubility must be calculated in order to predict this...because $K_{sp}$ s depend on how many of each ion are involved...cannot simply compare $K_{sp}$ s to compare AgI and $PbI_2$ !!)												
	52d	$CaF_2$												

Ch.	Q#	Answer/Comments
18	54	$K_{sp} = 5.4 \times 10^{-13} = [\text{Ag}^+][\text{Br}^-] = x^2$ ...where solubility of AgBr in pure water = $7.3 \times 10^{-7}$ mol/L, & note 1Br <sup>-</sup> , 1Ag <sup>+</sup> per AgBr... For a solution of 0.0065M Br <sup>-</sup> , helpful now to use ICE table along with $K_{sp}$ ... $K_{sp} = 5.4 \times 10^{-13} = x(0.0065 + x)$ with approximation = 0.0065x Solve for $x = 8.3 \times 10^{-11}$ mol/L, = [Ag <sup>+</sup> ] but also = solubility... Note much lower now! Common-ion effect.
18	58a 58b 58c	Ag <sub>2</sub> CO <sub>3</sub> PbCO <sub>3</sub> AgCN
18	60a 60b	Q = $2.4 \times 10^{-9} < K_{sp}$ therefore NiCO <sub>3</sub> will not precipitate Q = $2.4 \times 10^{-7} > K_{sp}$ therefore NiCO <sub>3</sub> will precipitate
18	64	[OH <sup>-</sup> ] = 0.0025 M; [Mg <sup>2+</sup> ] = 0.075 M; Q = $4.7 \times 10^{-7} > K_{sp}$ therefore Mg(OH) <sub>2</sub> will precipitate
18	66	when adding two sequential equilibrium reactions: add the reaction equations, but multiply the K's So: net rxn is $\text{AgI}(s) + 2 \text{CN}^-(aq) \rightleftharpoons \text{Ag}(\text{CN})_2^-(aq) + \text{I}^-(aq)$ $K_{net} = K_{sp} \text{ (for AgI)} \times K_{formation} \text{ (for Ag(CN)}_2^-) = 480$
18	74a 74b 74c 74d	pH > 7. The solution will contain the conjugate base of the weak acid (and counter ion...) pH > 7. The solution will contain the NH <sub>3</sub> /NH <sub>4</sub> <sup>+</sup> pair (a buffer!) pH = 7. The solution will contain neutral ions. pH = 7. The solution will contain neutral ions.
18	76	For CaF <sub>2</sub> to precipitate, Q must exceed $K_{sp} (5.3 \times 10^{-11}) = [\text{Ca}^{2+}][\text{F}^-]^2$ ... If [Ca <sup>2+</sup> ] <sub>eqm</sub> is fixed at $2.0 \times 10^{-3}$ , then to ppt, [F <sup>-</sup> ] <sub>eqm</sub> = squareroot ( $5.3 \times 10^{-11} / 2.0 \times 10^{-3}$ ) = $1.6 \times 10^{-4}$ M ⇒ any concentration of F <sup>-</sup> higher than $1.6 \times 10^{-4}$ M will make Q > $K_{sp}$ & lead to precipitation
18	78a 78b 78c 78d	use $K_b$ and ICE table ⇒ solve for $x = [\text{OH}^-] = 5.7 \times 10^{-4}$ M... so pH = 14 - pOH = 10.75 calculate moles of ethanolamine = $2.5 \times 10^{-4}$ mol; in total volume 0.0513 L; so [ethanolamine] = 0.049 M Find $K_a = K_w / K_b = 3.1 \times 10^{-10}$ ; use ICE table & $K_a$ to solve for $x = [\text{H}_3\text{O}^+] = 1.2 \times 10^{-6}$ M ⇒ pH = 5.91 At titration midpoint (half-way to equivalence point), [HOCH <sub>2</sub> CH <sub>2</sub> NH <sub>2</sub> ] = [HOCH <sub>2</sub> CH <sub>2</sub> NH <sub>3</sub> <sup>+</sup> ] therefore pH = pK <sub>a</sub> = 9.51 methyl red would be a good choice of indicator
18	80	$K_{sp} = [\text{Sr}^{2+}][\text{CO}_3^{2-}] = 5.6 \times 10^{-10} \dots = x^2$ , where x = solubility of SrCO <sub>3</sub> . solve $x = 2.4 \times 10^{-5}$ M thus, in 1L, have 3.5 mg of SrCO <sub>3</sub> dissolved in a saturated solution.
18	82	use H.-H. equation since is a buffer: given pH, can solve for ratio [HPO <sub>4</sub> <sup>2-</sup> ]/[H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> ] = 3.5 calculate moles H <sub>3</sub> O <sup>+</sup> added: 0.0160 mol because added HCl, a strong acid... The total H <sub>3</sub> O <sup>+</sup> available can be used to produce HPO <sub>4</sub> <sup>-</sup> (from H <sub>3</sub> O <sup>+</sup> + PO <sub>4</sub> <sup>3-</sup> ) and H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> (2H <sub>3</sub> O <sup>+</sup> + PO <sub>4</sub> <sup>2-</sup> ) Total H <sub>3</sub> O <sup>+</sup> = 0.160 mol = (mol HPO <sub>4</sub> <sup>2-</sup> + 2 × mol H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> ) = (3.5 × mol H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> + 2 × mol H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> ) So use this expression to solve for moles of H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> (now the only unknown...) = 0.010 mol Total mol PO <sub>4</sub> <sup>3-</sup> needed = mol HPO <sub>4</sub> <sup>2-</sup> + mol H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> = 0.0029 mol + 0.010 mol = 0.013 mol PO <sub>4</sub> <sup>3-</sup> Convert 0.013 mol Na <sub>3</sub> PO <sub>4</sub> into mass: 2.1g

Ch.	Q#	Answer/Comments
18	86a	0.0123 mol C <sub>6</sub> H <sub>5</sub> CO <sub>2</sub> H; 0.0104 mol NaC <sub>6</sub> H <sub>5</sub> CO <sub>2</sub> ; use H.-H. eqn to solve for buffer's pH: = 4.13
	86b	to lower pH to 4.00, must additional acid form C <sub>6</sub> H <sub>5</sub> CO <sub>2</sub> H. Use H.-H. to find #mol C <sub>6</sub> H <sub>5</sub> CO <sub>2</sub> H needed. Solve for x = 0.017 mol C <sub>6</sub> H <sub>5</sub> CO <sub>2</sub> H; but already have 0.0123 mol, so need (0.017-0.0123 mol) more... convert to mass = 0.5g extra C <sub>6</sub> H <sub>5</sub> CO <sub>2</sub> H needed
	86c	another way to do it would be to add some HCl to the original buffer until reaches pH of 4.00. to predict how much to add: use H.-H. eqn to find required A-/HA ratio = 0.63 $\frac{[\text{C}_6\text{H}_5\text{CO}_2^-]}{[\text{C}_6\text{H}_5\text{CO}_2\text{H}]} = \frac{\text{mol C}_6\text{H}_5\text{CO}_2^-}{\text{mol C}_6\text{H}_5\text{CO}_2\text{H}} = 0.63 = \frac{0.0104 - x}{0.0123 + x}$ solve for x, = 0.0016 mol H <sub>3</sub> O <sup>+</sup> needed thus: starting with 2.0M HCl, must add 8.2x10 <sup>-4</sup> L, or 0.82 mL
18	90	K <sub>sp</sub> = 4.9x10 <sup>-17</sup> = [Fe <sup>2+</sup> ][OH <sup>-</sup> ] <sup>2</sup> = (0.1)[OH <sup>-</sup> ] <sup>2</sup> ⇒ [OH <sup>-</sup> ] required to ppt Fe(OH) <sub>2</sub> (s) from soln = 2.2x10 <sup>-8</sup> M K <sub>sp</sub> = 1.4x10 <sup>-15</sup> = [Pb <sup>2+</sup> ][OH <sup>-</sup> ] <sup>2</sup> = (0.1)[OH <sup>-</sup> ] <sup>2</sup> ⇒ [OH <sup>-</sup> ] required to ppt Pb(OH) <sub>2</sub> (s) from soln = 1.2x10 <sup>-7</sup> M K <sub>sp</sub> = 1.3x10 <sup>-33</sup> = [Al <sup>3+</sup> ][OH <sup>-</sup> ] <sup>3</sup> = (0.1)[OH <sup>-</sup> ] <sup>3</sup> ⇒ [OH <sup>-</sup> ] required to ppt Al(OH) <sub>3</sub> (s) from soln = 2.4x10 <sup>-11</sup> M Thus, Al(OH) <sub>3</sub> will precipitate first, followed by Fe(OH) <sub>2</sub> , then Pb(OH) <sub>2</sub>
18	92	add the reactions: Zn(OH) <sub>2</sub> (s) + 2 CN <sup>-</sup> (aq) ⇌ Zn(CN) <sub>2</sub> (s) + 2OH <sup>-</sup> (aq) multiply the eqm constants: K <sub>net</sub> = K <sub>sp</sub> (for Zn(OH) <sub>2</sub> ) × K (for 2 <sup>nd</sup> rxn = 1/K <sub>sp</sub> for Zn(CN) <sub>2</sub> ) = 4x10 <sup>-6</sup> Thus: overall, the eqm lies to the left. We can tell that the transformation of zinc hydroxide into zinc cyanide will not occur to a large extent because of the unfavourable (small) equilibrium constant.
18	98	Ba(OH) <sub>2</sub> and BaCO <sub>3</sub>
18	102a	HB is a stronger acid than HA
	102b	A <sup>-</sup> is a stronger base than B <sup>-</sup> .
18	104a	As the pH increases, the first ionization equilibrium H <sub>2</sub> CO <sub>3</sub> (aq) + H <sub>2</sub> O(l) ⇌ HCO <sub>3</sub> <sup>-</sup> (aq) + H <sub>3</sub> O <sup>+</sup> (aq) shifts to the right and more HCO <sub>3</sub> <sup>-</sup> is produced. As the pH rises further, the second ionization occurs HCO <sub>3</sub> <sup>-</sup> (aq) + H <sub>2</sub> O(l) ⇌ CO <sub>3</sub> <sup>2-</sup> (aq) + H <sub>3</sub> O <sup>+</sup> (aq) and is shifted to the right with increasing pH, which decreases the amount of HCO <sub>3</sub> <sup>-</sup> present in the solution.
	104b	At pH = 6.0, the solution is 72% H <sub>2</sub> CO <sub>3</sub> and 28% HCO <sub>3</sub> <sup>-</sup> . At pH = 10.0, the solution is 66% HCO <sub>3</sub> <sup>-</sup> and 33% CO <sub>3</sub> <sup>2-</sup> .
	104c	A solution buffered at pH = 11.0 should have a HCO <sub>3</sub> <sup>-</sup> to CO <sub>3</sub> <sup>2-</sup> ratio of 0.2 to 1.
